Abstract

This clinical guideline on epilepsy contains levels of evidence and recommendations based on the scientific method. Its primary function is to provide emergency medicine physicians a clear diagnostic approach when faced with a pediatric or adult patient with epileptic seizures (ES) or epilepsy. The objective is to unify criteria that will guarantee integral health care, based on adequate decision-making, benefiting the patient through the individualized analysis of proper anamnesis, physical examination, precise indication of laboratory, and image diagnostic tests that yield the pertinent clinical and pharmacological treatment for opportune interventions, avoiding complications, and whenever possible, the recurrence of the ES.

Key words: Seizures. Epilepsy. Treatment in the emergency room.

Introduction

Epilepsy is one of the diseases that affect the quality of life of patients the most, due to its neurological, psychological, and social implications. Epileptic seizures (ES) are a common cause of admittance to the emergency room (ER), and they are responsible for 1 million or 1% of all the ER consults. The annual cost of care, prehospital and within the ER, to treat ES is estimated to be 1 billion dollars. Clinical guidelines attempt to direct and guarantee the assertiveness of medical attention to improve the diagnosis and treatment of this disease¹-³.

Recommendations for scientific research were based on the selective location of keywords in PubMed-MEDLINE, The Cochrane Library, and other clinical practice guidelines, as well as recommendations by other scientific societies.
Questions addressed within this guideline

1. What clinical data must be purposefully investigated during the anamnesis of a patient with ES in the ER?
2. Which laboratory tests must be performed in the ER on a patient with a first ES?
3. Under which conditions must electroencephalography be performed on a patient with ES in the ER?
4. Under which conditions must a neuroimaging test (CT or MRI) be performed on a patient with ES in the ER?
5. Under which conditions must anti-epileptic drugs be initiated on patients with a first ES in the ER?

ES: epileptic seizures; ER: emergency room; CT: computerized tomography; MRI: magnetic resonance imaging.

What clinical data must be purposefully investigated during the anamnesis of a patient with ES in the ER?

LP is recommended for any patient with a first ES and suspicion of CNS infection, subarachnoid hemorrhage determined by a non-diagnostic CT image, suspicion of HIV infection, or children under 6 months of age.

A LP is not indicated on patients who show complete recovery of their neurological basal state after a first ES.

To establish a differential diagnosis of non-epileptic paroxysmal events, individualization of cases is recommended when considering complementary tests.

If substance abuse of psychoactive drugs or exposure to toxic substances is suspected, a toxicology screen is recommended.

Complementary diagnostic tests after a new ES on patients with a known history of epilepsy are not necessary, unless there is suspicion of lack of pharmaceutical efficacy, intoxication, adherence to treatment, or change in seizure pattern.

LP: lumbar puncture; ES: epileptic seizures; CNS: central nervous system; CT: computerized tomography.
Under which conditions must electroencephalography be performed on a patient with ES in the ER?

| There is no evidence that an emergency EEG has any implication on immediate therapy; therefore, there are few indications such as:  
  - Suspicion of subtle or non-convulsive status epilepticus  
  - Comatose state of unknown origin  
  - Suspicion of herpetic encephalitis | IV  
  SAdE, 20156 |
| A routine EEG in the ER is not recommended for previously healthy patients (pediatric or adult) that present a first ES and have returned to their basal state | R-SAdE, 20156 |
| An EEG is a useful diagnostic test in stabilized patients in the ER to:  
  - Support the diagnosis of epilepsy  
  - Determine the type of epilepsy and epileptic syndrome, in concordance with clinical findings and  
    ictal activity  
  - Assess the risk of seizure recurrence  
  - Support therapeutic decisions | 2+  
  SIGN, 20157

<tr>
<td>A cranial CT must be performed on all emergency cases; however, it does not substitute a programmed cranial MRI</td>
<td>B SAdE, 2015^f</td>
</tr>
<tr>
<td>An emergency cranial CT may be considered for previously healthy patients (pediatric or adult) if a programmed MRI cannot be performed within the following 3 days</td>
<td>R-SAdE, 2015^g</td>
</tr>
</tbody>
</table>
Neuroimaging tests (cranial CT or MRI, the latter being the first choice) are recommended for patients who present a first ES under the following circumstances:

− Focal seizures
− Focal neurological deficit
− Persistent alteration in the level of consciousness
− Recent traumatic brain injury
− Cancer
− Suspicion of HIV infection/immunosuppression
− Hemorrhagic diathesis
− Children under 2 years of age
− Persistent cephalgia (headache)
− Meningeal signs
− Signs of intracranial hypertension

CT: computerized tomography; MRI: magnetic resonance imaging.

### Neuroimaging tests are not useful under the following circumstances:

− Febrile seizures
− Focal impaired awareness seizures
− ES with a proven metabolic origin

R-SAde, 2015

</table>
| **Before initiating treatment with AED on a patient with a first ES**, it is recommended to consider:  
− The probability of recurrence  
− The drugs efficacy and toxicity | C  
NICE, 2012  
R-Bergey G, 2016 |
| **Treatment with AED after a first ES must be individualized and assessed by a qualified professional** | A  
NICE, 2012  
R-Leone MA, 2016  
C  
NICE, 2012  
R-Bergey G, 2016 |
| It is recommended that AED treatment be initiated on patients with one or more of the following risk factors:  
− History of previous brain injury with remote symptomatic seizures  
− Focal ES  
− ES during sleep  
− Family history of ES  
− Abnormal neurological examination  
− Psychomotor delay  
− Status epilepticus  
− Abnormal EEG  
− Neuroimaging abnormalities | C  
NICE, 2012  
R-Michoulas AS, 2011  
R-Bergey G, 2016  
R-Ghofrani M, 2013  
R-Krumholz A, 2015 |
| During the initiation of AED treatment, it is recommended to consider the risk of seizure aggravation:  
− Phenytoin aggravates absence and myoclonic seizures  
− Carbamazepine and oxcarbamazepine exacerbate absence, myoclonic, and atonic seizures | D  
NICE, 2012  
R-SAde, 2015 |

AED: anti-epileptic drug; EEG: electroencephalography.
